

HAWAII PACIFIC UNIVERSITY

PHYS 2054: PRACTICE EXAM 1

Campus/Centre:	<input checked="" type="checkbox"/> Downtown campus <input type="checkbox"/> Loa Campus
-----------------------	---

Examination Day:	TBD	Examination Date:	TBD
Examination Time:	TBD	Duration:	80 min

Course Abbreviation & Number:	PHYS 2054
Course Title:	General Physics III

Name of Student: _____

Student Number: _____

INSTRUCTIONS TO CANDIDATES

1. This examination consists of 5 pages.
2. There are 8 conceptual and 8 quantitative questions in this examination. Answer ALL questions.
3. **All working must be shown.**
4. **Units must be shown.**
5. A list of selected formulae is provided below.

LIST OF SELECTED FORMULAE

<p style="text-align: center;">Interference / double slit</p> <div style="border: 1px solid black; padding: 5px;"> $\phi = k(r_2 - r_1) = \frac{2\pi}{\lambda_n}(r_2 - r_1)$ $d \sin \theta = m\lambda_n \quad (\text{constructive})$ $d \sin \theta = \left(m + \frac{1}{2}\right)\lambda_n \quad (\text{destructive})$ $E_p = 2E \left \cos \frac{\phi}{2} \right$ $I = I_0 \cos^2 \frac{\phi}{2}$ </div>	<p style="text-align: center;">Thin film interference</p> <div style="border: 1px solid black; padding: 5px;"> <p style="text-align: center;">0 or 2π phase shift</p> $2t = m\lambda_n \quad (\text{constructive})$ $2t = \left(m + \frac{1}{2}\right)\lambda_n \quad (\text{destructive})$ <p style="text-align: center;">π phase shift</p> $2t = \left(m + \frac{1}{2}\right)\lambda_n \quad (\text{constructive})$ $2t = m\lambda_n \quad (\text{destructive})$ </div>	<p style="text-align: center;">Diffraction gratings</p> <div style="border: 1px solid black; padding: 5px;"> $d \sin \theta = m\lambda_n$ <p style="text-align: center;">Xray diffraction</p> <div style="border: 1px solid black; padding: 2px;"> $2d \sin \theta = m\lambda$ </div> <p style="text-align: center;">Circular apertures</p> <div style="border: 1px solid black; padding: 2px;"> $\sin \theta_1 \approx 1.22 \frac{\lambda}{D}$ $\sin \theta_2 \approx 2.23 \frac{\lambda}{D}$ $\sin \theta_3 \approx 3.24 \frac{\lambda}{D}$ </div> </div>
<p style="text-align: center;">Single slit</p> <div style="border: 1px solid black; padding: 5px;"> $a \sin \theta = m\lambda_n$ $I = I_0 \left\{ \frac{\sin[(\pi a/\lambda) \sin \theta]}{(\pi a/\lambda) \sin \theta} \right\}^2$ </div>	<p style="text-align: center;">gamma</p> <div style="border: 1px solid black; padding: 5px;"> $\gamma = \frac{1}{\sqrt{1 - u^2/c^2}}$ </div>	<p style="text-align: center;">Length contraction</p> <div style="border: 1px solid black; padding: 5px;"> $L = \frac{L_p}{\gamma}$ </div>

Conceptual Section (Circle the correct answer)

- Monochromatic coherent light passing through two thin slits is viewed on a distant screen. Which of the following statements is true? [2]
 - The fringes are perfectly spaced at equal distances on the screen.
 - The fringes move closer together when the light intensity increases.
 - The fringes move farther apart when the distance to the screen increases.
 - The fringes move farther apart when the distance between the slits increases.
- A two-slit interference experiment is submerged in water and the fringes are displayed on a screen. Then the whole apparatus is removed from the water. How does the fringe pattern change? [2]
 - The fringes are closer together.
 - The fringes are farther apart.
 - The separation between fringes is unchanged.
 - It depends on which hemisphere the experiment was performed.
- The width in a single-slit diffraction experiment is increased. What happens to the distance between minima on a viewing screen? [2]
 - They stay the same width apart.
 - They move closer together.
 - They move farther apart.
 - They can move closer together or farther apart depending upon the wavelength.
- Why is a diffraction grating better than a two-slit setup for measuring wavelengths of light? [2]
 - The total light increases in intensity when it passes through the diffraction grating.
 - The equation to find the maxima for a diffraction grating is less complicated.
 - The diffraction grating acts more like a single slit with a large central maximum.
 - The intensity peaks formed by a diffraction grating are more narrow than a double slit's peaks.
- You are an observer on Earth. As the speed of a spaceship moving away from you begins to decrease, you observe [2]
 - the length of the spaceship gets shorter.
 - the length of the spaceship gets longer.
 - the length of the spaceship does not change.
 - the length of the spaceship gets either longer or shorter depending on its distance from you.
- An astronaut in an inertial reference frame measures a time interval Δt between her heartbeats. What will observers in all other inertial reference frames measure for the time interval between her heartbeats? [2]
 - Less than Δt .
 - More than Δt .
 - The same Δt .
 - Negative Δt .
- Monochromatic light strikes a metal surface and electrons are ejected from the metal. If the intensity of the light is decreased, what will happen to the ejection rate and maximum energy of the electrons? [2]
 - Lower ejection rate; lower maximum energy
 - Same ejection rate; same maximum energy
 - Same ejection rate; lower maximum energy
 - Lower ejection rate; same maximum energy
- If the accuracy in measuring the momentum of a particle increases, the accuracy in measuring its position will [2]
 - decrease.
 - remain the same.
 - increase.
 - It is impossible to say since the two measurements are independent.

Quantitative Section

1. Light with wavelength 442 nm passes through a double-slit system that has a slit separation distance of $d = 0.400$ mm. Determine how far away a screen must be placed so that dark fringes appear directly opposite both slits, with only one bright fringe between them.
 - (a) Determine separation distance between the two slits. [3]
 - (b) At this same distance, for what wavelength of light will the first-order bright fringes be observed at these same points on the screen with only two minima separating them? [3]

2. Solar cells are often coated with a transparent, thin film of silicon monoxide (SiO , $n_{\text{SiO}} = 1.45$) to minimize reflective losses from the surface. Suppose a silicon solar cell ($n_{\text{Si}} = 3.5$) is coated with a thin film of silicon monoxide for this purpose.
 - (a) Determine the minimum film thickness that produces the least reflection at a wavelength of 550 nm, near the center of the visible spectrum. [3]
 - (b) Suppose a solar cell's coating was incorrectly manufactured so that it has the most reflection at 550 nm. Determine the minimum film thickness that could produce this reflection. [3]

3. Red light of wavelength 633 nm from a helium–neon laser passes through a slit 0.350 mm wide. The diffraction pattern is observed on a screen 3.00 m away.
 - (a) What is the distance on the screen from the central maximum to the first minimum? [2]
 - (b) What is the distance on the screen from the central maximum to the second minimum? [2]
 - (c) What is the width of the first bright fringe beyond the central bright fringe? [2]

4. Three discrete spectral lines occur at angles of 10.1° , 13.7° , and 14.8° in the first-order spectrum of a grating spectrometer.
- (a) If the grating has 3660 slits/cm, what are the wavelengths of the light? [3]
- (b) At what angles are these lines found in the second-order spectrum? [3]
5. The first-order diffraction maximum is observed at 12.6° for a crystal having a spacing between planes of atoms of 0.250 nm.
- (a) What wavelength x-ray is used to observe this first-order pattern? [3]
- (b) How many orders can be observed for this crystal at this wavelength? [3]
6. The pupil of a cat's eye narrows to a vertical slit of width 0.500 mm in daylight. Assume the average wavelength of the light is 500 nm. What is the angular resolution for horizontally separated mice? [3]
7. A deep-space vehicle moves away from the Earth with a speed of $0.800c$. An astronaut on the vehicle measures a time interval of 3.00 s to rotate her body through 1.00 rev as she floats in the vehicle. What time interval is required for this rotation according to an observer on the Earth? [3]

8. A jet stream of particles is ejected by a galaxy. Such jet streams are believed to be evidence of supermassive black holes at the center of a galaxy. Suppose two jet streams of material from the center of a galaxy are ejected in opposite directions. Both jet streams move at $0.750c$ relative to the galaxy center. Determine the speed of one jet stream as observed by the other. [3]
9. The total energy of a proton ($m_p = 1.672 \times 10^{-27}$ kg) is twice its rest energy. Find the momentum of the proton. [3]
10. Lithium, beryllium, and mercury have work functions of 2.30 eV, 3.90 eV, and 4.50 eV, respectively. Light with a wavelength of 400 nm is incident on each of these metals. Find the maximum kinetic energy for the photoelectrons in each case. [3]
11. X-rays are scattered from a target at an angle of 55.0° with the direction of the incident beam. Find the wavelength shift of the scattered x-rays. (rest mass of an electron, $m_e = 9.109 \times 10^{-31}$ kg) [3]
